

Lecture 5: Gauss-Markov Theorem

Economics 326 — Introduction to Econometrics II

Vadim Marmer, UBC

What we have so far

\$

\$

- **Simple linear regression model:**

$$Y_i = \beta_0 + \beta_1 X_i + U_i,$$

$$E[U_i | \mathbf{X}] = 0,$$

$$\text{Var}(U_i | \mathbf{X}) = \sigma^2,$$

$$\text{Cov}(U_i, U_j | \mathbf{X}) = 0 \text{ for all } i \neq j.$$

- **OLS estimator:**

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (X_i - \bar{X}) Y_i}{\sum_{i=1}^n (X_i - \bar{X})^2}.$$

- **Unbiasedness:** $E[\hat{\beta}_1 | \mathbf{X}] = \beta_1.$

- **Variance:**

$$\text{Var}(\hat{\beta}_1 | \mathbf{X}) = \frac{\sigma^2}{\sum_{i=1}^n (X_i - \bar{X})^2}.$$

- **Question:** Is OLS the best we can do?

There are many alternative estimators

- The OLS estimator is not the only estimator we can construct.
- There are alternative estimators with some desirable properties.

Example of an alternative estimator

- Using only the first two observations, suppose that $X_2 \neq X_1$.

$$\tilde{\beta} = \frac{Y_2 - Y_1}{X_2 - X_1}.$$

- $\tilde{\beta}$ is **linear**:

$$\tilde{\beta} = c_1 Y_1 + c_2 Y_2,$$

where

$$c_1 = -\frac{1}{X_2 - X_1} \text{ and } c_2 = \frac{1}{X_2 - X_1}.$$

- Signal/noise decomposition of $\tilde{\beta}$:

$$\begin{aligned}\tilde{\beta} &= \frac{Y_2 - Y_1}{X_2 - X_1} \\ &= \frac{(\alpha + \beta X_2 + U_2) - (\alpha + \beta X_1 + U_1)}{X_2 - X_1} \\ &= \frac{\beta(X_2 - X_1)}{X_2 - X_1} + \frac{U_2 - U_1}{X_2 - X_1} \\ &= \beta + \frac{U_2 - U_1}{X_2 - X_1}.\end{aligned}$$

- Unbiasedness of $\tilde{\beta}$:

$$\begin{aligned}\mathbb{E}[\tilde{\beta} \mid \mathbf{X}] &= \beta + \mathbb{E}\left[\frac{U_2 - U_1}{X_2 - X_1} \mid \mathbf{X}\right] \\ &= \beta + \frac{\mathbb{E}[U_2 \mid \mathbf{X}] - \mathbb{E}[U_1 \mid \mathbf{X}]}{X_2 - X_1} \\ &= \beta.\end{aligned}$$

Optimality of an estimator: BLUE

- Among all **linear** and **unbiased** estimators, an estimator with the **smallest variance** is called the **Best Linear Unbiased Estimator (BLUE)**.

Gauss-Markov Theorem

Suppose that

- $Y_i = \alpha + \beta X_i + U_i$.
- $\mathbb{E}[U_i \mid \mathbf{X}] = 0$.
- $\mathbb{E}[U_i^2 \mid \mathbf{X}] = \sigma^2$ for all $i = 1, \dots, n$ (homoskedasticity).
- For all $i \neq j$, $\mathbb{E}[U_i U_j \mid \mathbf{X}] = 0$.

Then the OLS estimators are **BLUE**.

Gauss-Markov Theorem (setup)

- We already know that the OLS estimator $\hat{\beta}$ is linear and unbiased.
- Let $\tilde{\beta}$ be any other estimator of β such that
 - $\tilde{\beta}$ is linear:

$$\tilde{\beta} = \sum_{i=1}^n c_i Y_i,$$

where c 's depend only on $\mathbf{X}$.

- $\tilde{\beta}$ is unbiased: $\mathbb{E}[\tilde{\beta} \mid \mathbf{X}] = \beta$.

- We need to show that for **any** such $\tilde{\beta} \neq \hat{\beta}$,

$$\text{Var}(\tilde{\beta} \mid \mathbf{X}) > \text{Var}(\hat{\beta} \mid \mathbf{X}).$$

An outline of the proof

1. First, we are going to show that the c 's in $\tilde{\beta} = \sum_{i=1}^n c_i Y_i$ satisfy $\sum_{i=1}^n c_i = 0$ and $\sum_{i=1}^n c_i X_i = 1$.
2. Using the results of Step 1, we will show that $\text{Cov}(\tilde{\beta}, \hat{\beta} | \mathbf{X}) = \text{Var}(\hat{\beta} | \mathbf{X})$.
3. Using the results of Step 2, we will show that $\text{Var}(\tilde{\beta} | \mathbf{X}) \geq \text{Var}(\hat{\beta} | \mathbf{X})$.
4. Lastly, we will show that $\text{Var}(\tilde{\beta} | \mathbf{X}) = \text{Var}(\hat{\beta} | \mathbf{X})$ if and only if $\tilde{\beta} = \hat{\beta}$.

Proof: Step 1

- Since $\tilde{\beta} = \sum_{i=1}^n c_i Y_i$,

$$\begin{aligned}\tilde{\beta} &= \sum_{i=1}^n c_i (\alpha + \beta X_i + U_i) \\ &= \alpha \sum_{i=1}^n c_i + \beta \sum_{i=1}^n c_i X_i + \sum_{i=1}^n c_i U_i.\end{aligned}$$

- Therefore,

$$\begin{aligned}\mathbb{E}[\tilde{\beta} | \mathbf{X}] &= \mathbb{E}\left[\alpha \sum_{i=1}^n c_i + \beta \sum_{i=1}^n c_i X_i + \sum_{i=1}^n c_i U_i \mid \mathbf{X}\right] \\ &= \alpha \sum_{i=1}^n c_i + \beta \sum_{i=1}^n c_i X_i + \sum_{i=1}^n c_i \mathbb{E}[U_i | \mathbf{X}] \\ &= \alpha \sum_{i=1}^n c_i + \beta \sum_{i=1}^n c_i X_i.\end{aligned}$$

- From the **linearity** we have that

$$\mathbb{E}[\tilde{\beta} | \mathbf{X}] = \alpha \sum_{i=1}^n c_i + \beta \sum_{i=1}^n c_i X_i.$$

- From the **unbiasedness** we have that

$$\beta = \mathbb{E}[\tilde{\beta} | \mathbf{X}] = \alpha \sum_{i=1}^n c_i + \beta \sum_{i=1}^n c_i X_i.$$

- Since this has to be true for **any** α , β , and the X 's, it follows now that

$$\sum_{i=1}^n c_i = 0, \quad \sum_{i=1}^n c_i X_i = 1.$$

Proof: Step 2

- We have

$$\tilde{\beta} = \beta + \sum_{i=1}^n c_i U_i, \quad \text{with } \sum_{i=1}^n c_i = 0, \sum_{i=1}^n c_i X_i = 1.$$

$$\hat{\beta} = \beta + \sum_{i=1}^n w_i U_i, \quad \text{with } w_i = \frac{X_i - \bar{X}}{\sum_{j=1}^n (X_j - \bar{X})^2}.$$

- Then,

$$\begin{aligned}
\text{Cov}(\tilde{\beta}, \hat{\beta} \mid \mathbf{X}) &= \text{E}[(\tilde{\beta} - \beta)(\hat{\beta} - \beta) \mid \mathbf{X}] \\
&= \text{E}\left[\left(\sum_{i=1}^n c_i U_i\right) \left(\sum_{i=1}^n w_i U_i\right) \mid \mathbf{X}\right] \\
&= \sum_{i=1}^n c_i w_i \text{E}[U_i^2 \mid \mathbf{X}] + \sum_{i=1}^n \sum_{j \neq i}^n c_i w_j \text{E}[U_i U_j \mid \mathbf{X}].
\end{aligned}$$

- Since $\text{E}[U_i^2 \mid \mathbf{X}] = \sigma^2$ for all i 's:

$$\sum_{i=1}^n c_i w_i \text{E}[U_i^2 \mid \mathbf{X}] = \sigma^2 \sum_{i=1}^n c_i w_i.$$

- Since $\text{E}[U_i U_j \mid \mathbf{X}] = 0$ for all $i \neq j$,

$$\sum_{i=1}^n \sum_{j \neq i}^n c_i w_j \text{E}[U_i U_j \mid \mathbf{X}] = 0.$$

- Thus,

$$\text{Cov}(\tilde{\beta}, \hat{\beta} \mid \mathbf{X}) = \sigma^2 \sum_{i=1}^n c_i w_i.$$

and

$$w_i = \frac{X_i - \bar{X}}{\sum_{j=1}^n (X_j - \bar{X})^2}.$$

- We have:

$$\begin{aligned}
\text{Cov}(\tilde{\beta}, \hat{\beta} \mid \mathbf{X}) &= \sigma^2 \sum_{i=1}^n c_i \frac{X_i - \bar{X}}{\sum_{j=1}^n (X_j - \bar{X})^2} \\
&= \frac{\sigma^2}{\sum_{j=1}^n (X_j - \bar{X})^2} \sum_{i=1}^n c_i (X_i - \bar{X}) \\
&= \frac{\sigma^2}{\sum_{j=1}^n (X_j - \bar{X})^2} \left(\sum_{i=1}^n c_i X_i - \bar{X} \sum_{i=1}^n c_i \right) \\
&= \frac{\sigma^2}{\sum_{j=1}^n (X_j - \bar{X})^2} (1 + \bar{X} \cdot 0) \\
&= \text{Var}(\hat{\beta} \mid \mathbf{X}).
\end{aligned}$$

Proof: Step 3

- We know now that for any **linear** and **unbiased** $\tilde{\beta}$,

$$\text{Cov}(\tilde{\beta}, \hat{\beta} \mid \mathbf{X}) = \text{Var}(\hat{\beta} \mid \mathbf{X}).$$

- Let's consider $\text{Var}(\tilde{\beta} - \hat{\beta} \mid \mathbf{X})$:

$$\begin{aligned}
\text{Var}(\tilde{\beta} - \hat{\beta} \mid \mathbf{X}) &= \text{Var}(\tilde{\beta} \mid \mathbf{X}) + \text{Var}(\hat{\beta} \mid \mathbf{X}) - 2\text{Cov}(\tilde{\beta}, \hat{\beta} \mid \mathbf{X}) \\
&= \text{Var}(\tilde{\beta} \mid \mathbf{X}) + \text{Var}(\hat{\beta} \mid \mathbf{X}) - 2\text{Var}(\hat{\beta} \mid \mathbf{X}) \\
&= \text{Var}(\tilde{\beta} \mid \mathbf{X}) - \text{Var}(\hat{\beta} \mid \mathbf{X}).
\end{aligned}$$

- But since $\text{Var}(\tilde{\beta} - \hat{\beta} \mid \mathbf{X}) \geq 0$,

$$\text{Var}(\tilde{\beta} \mid \mathbf{X}) - \text{Var}(\hat{\beta} \mid \mathbf{X}) \geq 0$$
or

$$\text{Var}(\tilde{\beta} \mid \mathbf{X}) \geq \text{Var}(\hat{\beta} \mid \mathbf{X}).$$

Proof: Step 4 (Uniqueness)

Suppose that $\text{Var}(\tilde{\beta} \mid \mathbf{X}) = \text{Var}(\hat{\beta} \mid \mathbf{X})$.

- Then,

$$\text{Var}(\tilde{\beta} - \hat{\beta} \mid \mathbf{X}) = \text{Var}(\tilde{\beta} \mid \mathbf{X}) - \text{Var}(\hat{\beta} \mid \mathbf{X}) = 0.$$
- Thus, $\tilde{\beta} - \hat{\beta}$ is not random or

$$\tilde{\beta} - \hat{\beta} = \text{constant}.$$
- This constant also has to be zero because

$$\begin{aligned} \text{E}[\tilde{\beta} \mid \mathbf{X}] &= \text{E}[\hat{\beta} \mid \mathbf{X}] + \text{constant} \\ &= \beta + \text{constant}, \end{aligned}$$
and in order for $\tilde{\beta}$ to be **unbiased**

$$\text{constant} = 0 \text{ or } \tilde{\beta} = \hat{\beta}.$$

Why does unbiasedness matter?

- The Gauss-Markov Theorem says that OLS is the best among **linear unbiased** estimators. Can we do better if we drop unbiasedness?
- Consider $\tilde{\beta} = 0$ (always “estimate” the slope as zero, regardless of the data).
- $\tilde{\beta} = 0$ is **linear**: $\tilde{\beta} = \sum_{i=1}^n 0 \cdot Y_i = 0$.
- $\tilde{\beta} = 0$ is **biased**: $\text{E}[\tilde{\beta} \mid \mathbf{X}] = 0 \neq \beta$ (unless $\beta = 0$).
- $\text{Var}(\tilde{\beta} \mid \mathbf{X}) = 0 < \text{Var}(\hat{\beta} \mid \mathbf{X})$.
- So $\tilde{\beta} = 0$ has a **smaller variance** than OLS, but it is useless as an estimator because it ignores the data entirely.
- This illustrates why the **unbiasedness** requirement in the Gauss-Markov Theorem is essential: without it, one can trivially achieve zero variance by using a constant.

What if homoskedasticity fails?

- Suppose that $\text{E}[U_i^2 \mid \mathbf{X}] = \sigma^2(X_i) = \sigma_i^2$, where σ_i^2 may differ across observations (**heteroskedasticity**).
- **Unbiasedness** of the OLS estimator $\hat{\beta}$ **still holds**. The proof of unbiasedness only uses:
 1. $Y_i = \alpha + \beta X_i + U_i$.
 2. $\text{E}[U_i \mid \mathbf{X}] = 0$.

It does **not** require homoskedasticity.

- However, the OLS estimator is **no longer BLUE**.
- The Gauss-Markov proof relied on $\text{E}[U_i^2 \mid \mathbf{X}] = \sigma^2$ being the **same** for all i 's.
- There exists another linear unbiased estimator with a **smaller variance** than OLS.

Transforming the model

- Suppose we know $\sigma_i^2 = \text{Var}(U_i | \mathbf{X})$ for each i . Divide both sides of $Y_i = \alpha + \beta X_i + U_i$ by σ_i :

$$\frac{Y_i}{\sigma_i} = \alpha \cdot \frac{1}{\sigma_i} + \beta \cdot \frac{X_i}{\sigma_i} + \frac{U_i}{\sigma_i}.$$

- Define the **transformed variables**:

$$Y_i^* = \frac{Y_i}{\sigma_i}, \quad X_{0i}^* = \frac{1}{\sigma_i}, \quad X_{1i}^* = \frac{X_i}{\sigma_i}, \quad U_i^* = \frac{U_i}{\sigma_i}.$$

- The transformed model is:

$$Y_i^* = \alpha X_{0i}^* + \beta X_{1i}^* + U_i^*.$$

- The transformed errors U_i^* satisfy:

$$- \text{E}[U_i^* | \mathbf{X}] = \frac{1}{\sigma_i} \text{E}[U_i | \mathbf{X}] = 0.$$

$$- \text{Var}(U_i^* | \mathbf{X}) = \frac{1}{\sigma_i^2} \text{Var}(U_i | \mathbf{X}) = \frac{\sigma_i^2}{\sigma_i^2} = 1.$$

- The transformed errors are **homoskedastic**: $\text{Var}(U_i^* | \mathbf{X}) = 1$ for all i 's.
- The Gauss-Markov assumptions hold for the transformed model, so OLS applied to the **transformed** data is **BLUE**.

Weighted Least Squares (WLS)

- OLS applied to the transformed model minimizes (w.r.t. a and b):

$$\sum_{i=1}^n \frac{(Y_i - a - bX_i)^2}{\sigma_i^2} = \sum_{i=1}^n w_i (Y_i - a - bX_i)^2,$$

where $w_i = 1/\sigma_i^2$.

- This is called **Weighted Least Squares (WLS)**.
- Interpretation**: WLS gives **more weight** to observations with smaller variance (more precise observations) and **less weight** to observations with larger variance (noisier observations).
- The WLS estimator is BLUE for β in the original model.
- The WLS estimator of β is:

$$\hat{\beta}_{WLS} = \frac{\sum_{i=1}^n w_i (X_i - \bar{X}_w)(Y_i - \bar{Y}_w)}{\sum_{i=1}^n w_i (X_i - \bar{X}_w)^2},$$

where $w_i = 1/\sigma_i^2$, $\bar{X}_w = \frac{\sum_{i=1}^n w_i X_i}{\sum_{i=1}^n w_i}$, and $\bar{Y}_w = \frac{\sum_{i=1}^n w_i Y_i}{\sum_{i=1}^n w_i}$.

- Practical limitation**: WLS requires knowledge of σ_i^2 , which is typically unknown.
